BUSINESS PROCESS ANALYSIS OF INFORMATION SYSTEMS PT. RINDANG SAKTI PERSADA

In this developing era, technology has become a mandatory requirement for society. Meriam Webster argues that technology is an implementation of substantial knowledge, especially in a specific process by carrying out tasks to completion, especially by applying technical steps, methods, or knowledge. As well as specific factors from certain parts of the business.

Until now, companies that implement or implement technology into business facilities are increasing, of course to be able to get more users from a wider area. Because actually technology is useful for facilitating achievements and facilitating various activities that exist in human life every day. The implementation of an information system within the company aims to maximize efficiency and optimize when doing work accurately and in real time.

To support and optimize the technology applied in a company, of course, requires an information system business process in a company to make it easier to make sales or purchases within a company. This can provide a solution that has been complained by several companies where there are a number of items that are not in sync with the stock available so that with an information system work can take place optimally, quickly and correctly and structured so as to minimize things that can harm the company.

The company optimizes the supervision process with the hope that later business needs that are strongly related to this technology can be carried out smoothly without any obstacles and can be completed in a short time, if later the company faces several technical problems that require renovations to be carried out as quickly as possible.
